Abstract. Based on the secant equations proposed by Zhang, Deng and Chen, we propose a new nonlinear conjugate gradient method for unconstrained optimization problems. Global convergence of this method is established under some proper conditions.

Keywords: Unconstrained optimization problem, modified secant equations, conjugate gradient method, global convergence.

1. Introduction

Conjugate gradient method plays a specific role in solving large-scale nonlinear minimization problems. Some good references of the conjugate gradient methods can be found in many research. In the past few years, many efforts have been made to research new conjugate gradient methods which process not only the global convergence property for general functions but also good numerical performances. Many of these new conjugate gradient methods are based on the secant equations ([10,11]).

In this paper, we present a conjugate gradient method to solve the following unconstrained optimization problem

$$\min_{x \in R^n} f(x), \quad (1)$$

where $f: R^n \rightarrow R$ is a smooth nonlinear function.

The iterative formula is

$$x_{k+1} = x_k + s_k, \quad s_k = \alpha_k d_k, \quad (2)$$

where α_k is the step size which is computed by some line search([1]). The search direction d_k is defined by

$$d_k = \begin{cases} -g_k, & k=0, \\ -g_k + \beta_k d_k, & k \geq 1, \end{cases} \quad (3)$$

where β_k is a scalar and $g_k = \nabla f(x)$ is the gradient of $f(x)$.

Remark Here, we use the strong Wolf line search condition (see[1]), that is, the step size α_k satisfies

$$\begin{aligned} f(x_k + \alpha d_k) - f(x_k) &\leq \delta \alpha_k g_k^T d_k, \\ |g(x_k + \alpha d_k)^T d_k| &\leq -\sigma g_k^T d_k, \end{aligned} \quad (4)$$

where $0 < \delta < \sigma < 1$.

The gradient method proposed in this paper is based on a modified secant equations. Therefore, let us introduce shortly the secant equations firstly.

Note $G_k = \nabla^2 f(x_k)$, the matrix B_k is the approximation of G_k .

The secant equations is defined as follows:

$$B_{k+1} s_k = y_k, \quad (5)$$

where $s_k = x_{k+1} - x_k$, $y_k = g_{k+1} - g_k$. (5) sometimes is said to be the standard secant equations.

Definition 1 A twice continuously differentiable function f is said to be uniformly convex on the nonempty open convex set S if and only if there exists some constant $M > 0$ such that

$$(g(x) - g(y))^T (x - y) \geq M \|x - y\|^2, \quad \forall x, y \in S.$$

2. The new conjugate gradient method and the global convergence

In this paper we assume $g_k \neq 0$, otherwise the current point x_k is the stationary point of the problem (1).

Definition 2 It is said that the descent condition holds for the conjugate gradient method, if

$$g_k^T d_k < 0, \quad \forall k \geq 1,$$

and sufficient descent condition holds for the conjugate gradient method, if

$$g_k^T d_k < -c \|g_k\|^2, \quad \forall k \geq 1,$$

To discuss the validity and the global convergence of the new conjugate gradient method, we make the following basic assumptions for the objective function.

H 1 The level set $L = \{x \mid f(x) < f(x_1)\}$ is bounded, that is, there exists a constant B such that

$$\|x\| \leq B, \quad \forall x \in L. \quad (6)$$

H 2 In some neighborhood N of L , $L \subseteq N$, the function f is continuously differentiable, its gradient is Lipschitz continuous, that is there exists a constant L such that

$$\|\nabla f(x) - \nabla f(y)\| \leq L \|x - y\|, \quad \forall x \in N. \quad (7)$$

The following proposition is obtained by [5] directly.

Proposition 1 If f satisfies assumptions $H 1$ and $H 2$, then there exists a constant $\gamma > 0$ such that

$$\|\nabla f(x)\| \leq \gamma, \quad \forall x \in L. \quad (8)$$

For any conjugate gradient method which satisfies the strong Wolf line search conditions, we have the following general conclusions, see[3].

Lemma 1 Assume that the assumptions $H 1$ and $H 2$ hold. For the conjugate gradient method (2)-(3), where d_k is the descent direction, α_k is computed by the strong Wolf line search conditions, if

$$\sum_{k \geq 1} \frac{1}{\|d_k\|^2} = \infty, \quad (9)$$

then

$$\lim_{k \rightarrow \infty} \|g_k\| = 0. \quad (10)$$

Firstly, let us describe the modified secant equations in [6,7], it has better theory properties than the standard secant equations ([8]). Based on the modified secant equations, the relevant conjugate gradient method is proposed, and then the global convergence is discussed.

Supposed that the objective function f is smooth enough. We make its Taylor expansion at point $x_{k-1} = x_k - s_{k-1}$,

$$\begin{aligned} f_{k-1} &= f_k - s_{k-1}^T g_k + \frac{1}{2} s_{k-1}^T G_k s_{k-1} - \frac{1}{6} s_{k-1}^T (T_k s_{k-1}) s_{k-1} + O(\|s_{k-1}\|^4), \\ s_{k-1}^T g_{k-1} &= s_{k-1}^T g_k - s_{k-1}^T G_k s_{k-1} + \frac{1}{2} s_{k-1}^T (T_k s_{k-1}) s_{k-1} + O(\|s_{k-1}\|^4), \end{aligned}$$

where

$$s_{k-1}^T (T_k s_{k-1}) s_{k-1} = \sum_{i,j,l=1}^n \frac{\partial^3 f(x_k)}{\partial x^i \partial x^j \partial x^l} s_{k-1}^i s_{k-1}^j s_{k-1}^l, \quad (11)$$

The formula can be written as (see Zhang and Xu [7])

$$s_{k-1}^T G s_{k-1} = s_{k-1}^T y_{k-1} + \theta_{k-1}, \quad (12)$$

where

$$\theta_{k-1} = 6(f_{k-1} - f_k) + 3(g_{k-1} - g_k)^T s_{k-1}. \quad (13)$$
